Write a background process to capture shell commands entered on xv6 shell.

INTRODUCTION

xv6, being a UNIX like operating system uses system calls to interface between the user program and the system. The shell is an ordinary program that reads commands from the user and executes them, and is the primary user interface to traditional Unix-like systems. The fact that the shell is a user program, not part of the kernel, illustrates the power of the system call interface: there is nothing special about the shell. It also means that the shell is easy to replace; as a result, modern Unix systems have a variety of shells to choose from, each with its own user interface and scripting features. The xv6 shell is a simple implementation of the essence of the Unix Bourne shell. Interacts with the kernel through system calls.

Whenever we type a command in xv6 shell , the main loop reads the input on the command line using `getcmd` function in `sh.c`. Then it calls `fork`, which creates a copy of the shell process. The parent shell calls `wait`, while the child process runs the command. The `getcmd` function just takes input whatever you type in the xv6 shell.

A file descriptor is a small integer representing a kernel-managed object that a process may read from or write to. A process may obtain a file descriptor by opening a file, directory, or device, or by creating a pipe, or by duplicating an existing descriptor. By convention, a process reads from file descriptor 0 (standard input), writes output to file descriptor 1 (standard output), and writes error messages to file descriptor 2 (standard error).

The `exit` system call causes the calling process to stop executing and to release resources such as memory and open files.

The call `write(fd, buf, n)` writes `n` bytes from `buf` to the file descriptor `fd` and returns the number of bytes written. Fewer than `n` bytes are written only when an error occurs. `write` writes data at the current file offset and then advances that offset by the number of bytes written: each `write` picks up where the previous one left off.

IMPLEMENTATION

It can be implemented by editing user mode process `sh.c` file . Creating a file and opening it using `open` system call with parameters filename as `history` and setting flags `O_CREATE` and `O_APPEND`. The `O_CREATE` flag creates the file and `O_APPEND` flag writes and appends command to the end of the file . Then we check that the `fd` is greater than zero , so that indicates that file has been created and we are ready to write in it. We write into the file using `write()` system call .

We compare with size of the string and size of the buffer , if fewer than `n` bytes are written , it will fail to write in the file `history` . It will exit from the loop using `exit()` system call by stopping execution . To write in a file clearly , so that no overlapping of leeter occurs , after

every command “\n” is concatenated . Then atlast we close the file using *close()* system call .

CODE

We can do this by editing user mode process *sh.c* file .

In *getcmd* function ,

```
int fd;
fd = open("history_dump", O_CREATE | O_APPEND);
if(fd >= 0)
{
    printf(1, "File Created\n");
}
else
{
    printf(1, "Error : Failed to Create\n");
    exit();
}

char *str = strcat(buf, "\n");
int size = strlen(str);

if(write(fd, str, size) != size)
{
    printf(1, "Error : Failed to write on File\n");
    exit();
}
printf(1, "Written\n");
close(fd);
```

Points

- *fd = open("history", O_CREATE | O_APPEND);*
opens or creates and opens the file of name “*history*”
- flags used : *O_CREATE* and *O_APPEND*
- *O_CREATE* : creates the file
- *O_APPEND* : before each write, the file offset is positioned at the end of the file
- *str* – concatenates the commands that entered in shell(stored in *buf*) with “\n”
- *size* – size of the *str*.
- *write(fd, str, size)* – writes the *n* bytes (depends on *size*) from *str* to the file descriptor *fd* and returns bnumber of bytes written
- *close(fd)* - closes file descriptor

And we can read the contents from the file “*history_dump*” by adding system call *history*.

CODE

```
#include "types.h"
#include "user.h"
#include "stat.h"
#include "fcntl.h"

int main(void)
{
    int fd;
    //int ctr=1;
    static char buf[100];
    fd=open("history_dump",O_RDWR);
    read(fd,buf,500);

    printf(1,buf);

    exit();
}
```

Add strcat function ,

- Open *ulib.c* and *string.c* . Add the code
- Add definition of strcat in *user*.

CODE

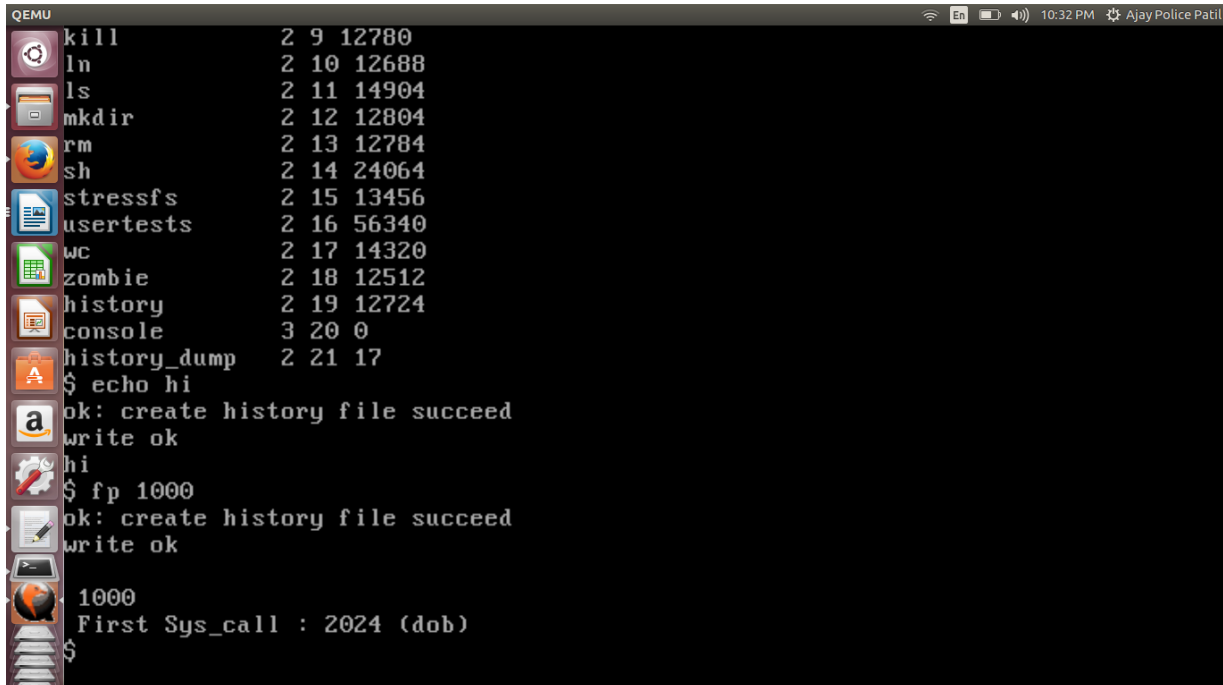

```
char* strcat(char* s1, const char* s2)
{
    char* b = s1;

    while (*s1) ++s1;
    while (*s2) *s1++ = *s2++;
    *s1 = 0;

    return b;
}
```

OUTPUT

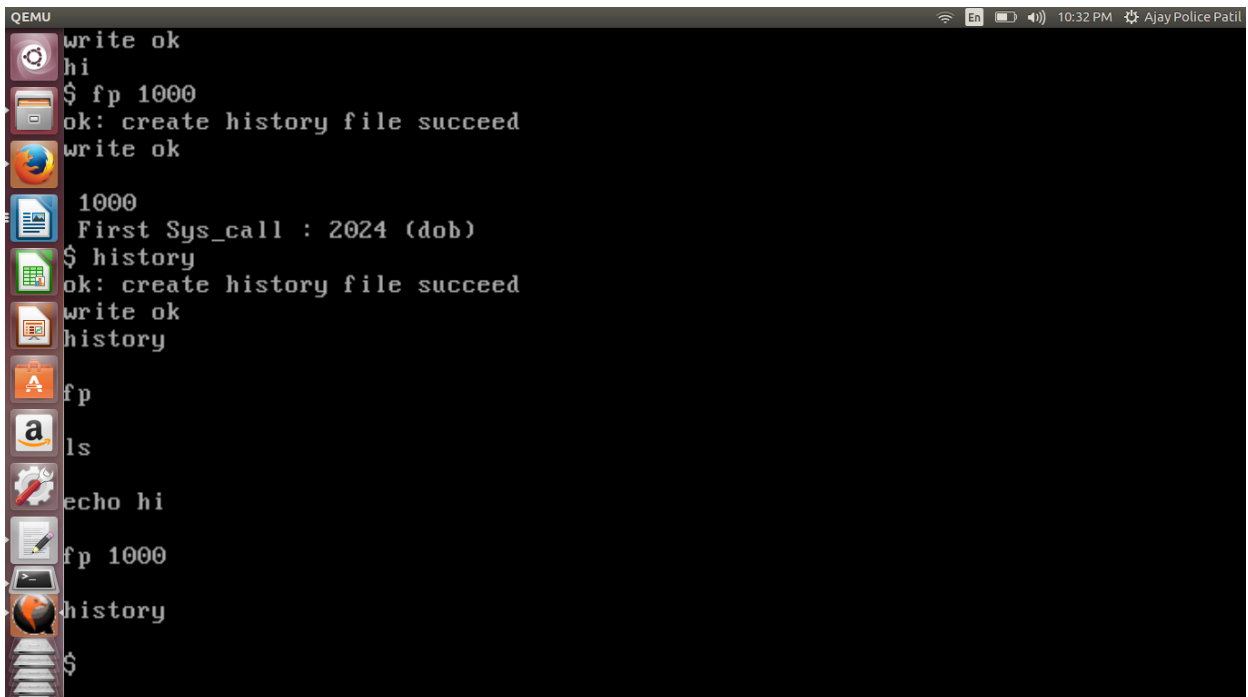

```
$ echo hi  
$ fp 1000
```

A screenshot of a QEMU terminal window. The window title is 'QEMU'. The top status bar shows 'En', a battery icon, a speaker icon, the time '10:32 PM', and the user 'Ajay Police Patil'. The terminal displays a list of processes with their PIDs, PPIDs, and memory addresses. Below the list, the user enters the command '\$ echo hi', followed by 'ok: create history file succeed' and 'write ok'. Then, the user enters '\$ fp 1000', followed by 'ok: create history file succeed' and 'write ok'. The terminal then shows '1000' and 'First Sys_call : 2024 (dob)'. The prompt '\$' is visible at the bottom.

```
kill          2  9 12780  
ln            2 10 12688  
ls           2 11 14904  
mkdir        2 12 12804  
rm           2 13 12784  
sh           2 14 24064  
stressfs     2 15 13456  
usertests    2 16 56340  
wc           2 17 14320  
zombie       2 18 12512  
history      2 19 12724  
console      3 20  0  
history_dump 2 21 17  
$ echo hi  
ok: create history file succeed  
write ok  
hi  
$ fp 1000  
ok: create history file succeed  
write ok  
1000  
First Sys_call : 2024 (dob)  
$
```

```
$ history
```

A screenshot of a QEMU terminal window. The window title is 'QEMU'. The top status bar shows 'En', a battery icon, a speaker icon, the time '10:32 PM', and the user 'Ajay Police Patil'. The terminal displays the history of commands entered. The commands are: 'write ok', 'hi', '\$ fp 1000', 'ok: create history file succeed', 'write ok', '1000', 'First Sys_call : 2024 (dob)', '\$ history', 'ok: create history file succeed', 'write ok', 'history', 'fp', 'ls', 'echo hi', 'fp 1000', and 'history'. The prompt '\$' is visible at the bottom.

```
write ok  
hi  
$ fp 1000  
ok: create history file succeed  
write ok  
1000  
First Sys_call : 2024 (dob)  
$ history  
ok: create history file succeed  
write ok  
history  
fp  
ls  
echo hi  
fp 1000  
history  
$
```

Further Improvement :

- We can add a system call to capture shell commands
- We can implement with arrow keys ( & ) to capture recently used command.
